Let $G$ be an abelian group, there there is a natural important homomorphism $m : G 	o G$ by $m(x) := mx$ for $m \in \mathbb{N}$. The image is denoted $mG$ and kernel is denoted $G[m]$. Let $G(p) = \{ u \in G | o(u) = p^n \text{ for some } n \geq 0 \}$. One can show that $G(p)$ is the Sylow $p$-subgroup of $G$. And $G$ is a direct sum of Sylow subgroups. Thus it remains to study finite abelian $p$-groups. The only non-trivial part of classical theory is showing that a finite abelian $p$-group is a direct sum of cyclic $p$-groups.

We also remark that for a given finitely generated abelian group $G$, the rank, invariant factors, and elementary divisors are unique. To see this, we proceed as following steps:

1. if $\mathbb{Z}^n \cong \mathbb{Z}^m$, then $n = m$.
   To see this, let $G \cong \mathbb{Z}^n \cong \mathbb{Z}^m$. We consider $G/2G \cong \mathbb{Z}^n_2 \cong \mathbb{Z}^m_2$. Thus $n = m$.
2. let $G_{tor} := \{ u \in G | mu = 0 \text{ for some } m \}$. It’s clear that $G_{tor} < G$.
3. If
   \[
   G_1 = \mathbb{Z}_{d_1} \oplus \ldots \oplus \mathbb{Z}_{d_t} \oplus \mathbb{Z}^r,
   \]
   \[
   \cong G_2 = \mathbb{Z}_{d'_1} \oplus \ldots \oplus \mathbb{Z}_{d'_t} \oplus \mathbb{Z}^{r'}
   \]
   Then clearly, $G_{1tor} \cong G_{2tor}$ and also $G_1/G_{1tor} = \mathbb{Z}^r \cong G_2/G_{2tor} = \mathbb{Z}^{r'}$. Hence in particular $r = r'$.
4. It remains to show that $t = t'$ and $d_i = d'_i$.
   To see this, it’s equivalent to show the uniqueness of elementary divisors of finite abelian groups. So now we assume that $G$ is finite abelian group. Also note that if $G_1 \cong G_2$, then $G_1(p) \cong G_2(p)$. Thus we may even assume that $G$ is a finite abelian $p$-group.

Suppose now that

\[
G_1 := \mathbb{Z}_{p^{a_1}} \oplus \ldots \oplus \mathbb{Z}_{p^{a_t}}
\]
\[
\cong G_2 := \mathbb{Z}_{p^{b_1}} \oplus \ldots \oplus \mathbb{Z}_{p^{b_s}},
\]
with $a_1 \leq a_2 \leq \ldots \leq a_t, b_1 \leq b_2 \leq \ldots \leq b_s$.

Then we have $pG_1 \cong pG_2$ and $G_1/pG_1 \cong G_2/pG_2$. Note that $G_1/pG_1 \cong \mathbb{Z}_{p^{c_1}}$, with $c_1 = \{i | a_i > 1\}$. It follows that $c_1(G_1) = c_1(G_2)$. Similarly, we can define $c_k := \{i | a_i > k\}$ and $c_k(G_1) = c_k(G_2)$.

Moreover, $G_1[p] \cong \mathbb{Z}_{p^t} \cong G_2[p] \cong \mathbb{Z}_{p^s}$. Hence $t = s$.

Since $t, c_1(G_1), c_2(G_1)\ldots$ determine $a_1, \ldots, a_t$ uniquely and $s, c_1(G_2), c_2(G_2)\ldots$ determine $b_1, \ldots, b_s$ uniquely. It follows that $t = s$ and $a_i = b_i$ for all $i$.

2.8. Nilpotent groups, solvable groups. Given a group $G$, if $G$ has a normal subgroup $N$, then we have a quotient group $G/N$. One can expect that knowing $N$ and $G/N$ would give some information on $G$. In this section, we are going to introduce the general technique of this idea.

Let $G$ be a group. If $G$ has no non-trivial normal subgroup, then $G$ is said to be simple.

In general, there are two natural way to produce normal subgroups. The first one is the center $Z(G)$. It is a normal subgroup of $G$. And we have the canonical projection $G \to G/Z(G)$. Let $C_2(G)$ be the inverse image of $Z(G/Z(G))$ in $G$. By the correspondence theorem, $Z(G/Z(G))$ is a normal subgroup of $G/Z(G)$ hence $C_2(G)$ is a normal subgroup of $G$. And then let $C_3(G)$ to be the inverse image of $Z(G/C_2(G))$. By doing this inductively, one has an ascending chain of normal subgroups

$$\{e\} < C_1(G) := Z(G) < C_2(G) < \ldots$$

Notice that by the construction, each $C_i(G) \triangleleft G$ and $C_{i+1}(G)/C_i(G)$ is abelian.

**Definition 2.8.1.** $G$ is nilpotent if $C_n(G) = G$ for some $n$.

**Proposition 2.8.2.** A finite $p$-group is nilpotent.

**Proof.** We use the fact that a finite $p$-group has non-trivial center. Thus one has $C_i \leq C_{i+1}$. The group $G$ has finite order thus the ascending chain must terminates, say at $C_n$. If $C_n \neq G$, then $G/C_n$ has non-trivial center. One has $C_n \leq C_{n+1}$ which is impossible. Hence $C_n = G$. □

**Theorem 2.8.3.** If $H, K$ are nilpotent, so is $H \times K$.

**Proof.** The key observation is that $Z(H \times K) = Z(H) \times Z(K)$. Then inductively, one proves that $C_i(H \times K) = C_i(H) \times C_i(K)$. If $C_n(H) = H, C_m(K) = K$ then $C_l(H \times K)$ for $l = \max(m, n)$. □

**Lemma 2.8.4.** Let $G$ be a nilpotent group and $H \leq G$ be a proper subgroup. Then $H \leq N_G(H)$.

**Proof.** Let $C_0(G) = \{e\}$. Let $k$ be the largest index such that $C_k(G) < H$. Then $C_{k+1}(G) \not\leq H$. Pick $a \in C_{k+1} - H$, then for every $h \in H$, we have $C_k ha = C_k h C_k a = C_k a C_k h = C_k a h$ for $C_{k+1}/C_k = Z(G/C_k(G))$. Thus $aha^{-1} \in C_k h \subset H$ for all $h \in H$. That is $a \in N_G(H) - H$. □

Then we are ready to prove the following:

**Theorem 2.8.5.** A finite group is nilpotent if and only if it’s a direct product of Sylow $p$-subgroups.

**Proof.** By the previous two results, it’s clear that a direct product of Sylow $p$-subgroups is nilpotent.
Conversely, if $G$ is nilpotent, then we will prove that every Sylow $p$-subgroup is a normal subgroup of $G$. By checking the decomposition criterion, one has the required decomposition.

It remains to show that if $P$ is Sylow $p$-subgroup, then $P \triangleleft G$.

To this end, it suffices to prove that $N_G(P) = G$. By applying this Claim to $N_G(P)$, then it says that $N_G(P)$ can’t be a proper subgroup of $G$ since $N_G(N_G(P)) = N_G(P)$. Thus it follows that $N_G(P) = G$. □

Example 2.8.6.

Let $G = D_{12} = \{x^iy^j | x^6 = y^2 = e, xy = yx^5\}$. One of its Sylow 2-subgroup is $\{e, x^3, y, x^3y\}$ isomorphic to $V_4$ and it’s Sylow 3-subgroup is $\{e, x^2, x^4\} \cong \mathbb{Z}_3$.

However $Z(G) = \{e, x^3\}$ and $G/Z(G) \cong D_6 \cong S_3$ and $Z(S_3) = \{e\}$. Thus $G$ is not nilpotent. And therefore, $D_{12} \not\cong V_4 \times \mathbb{Z}_3$. □

We have seen that we have a series of subgroup by taking centers. Another natural construction is to take commutators.

Definition 2.8.7. Let $G$ be a group. The commutator of $G$, denoted $G'$ is the subgroup generated by the subset $\{aba^{-1}b^{-1} | a, b \in G\}$.

Roughly speaking, the subgroup $G'$ measures the non-commutativity of a group. More precisely, $G' = \{e\}$, if and only $G$ is abelian. The smaller $G'$, the more commutative it is.

Proposition 2.8.8. We have:

1. $G' \triangleleft G$,
2. and $G/G'$ is abelian.
3. if $N \triangleleft G$, then $G/N$ is abelian if and only if $G' < N$.

Proof. 1.) for all $g \in G$, $g(aba^{-1}b^{-1})g^{-1} \in G'$, hence $gG'g < G'$. So $G' \triangleleft G$.

2.) $aG'bg = abG' = ab(b^{-1}a^{-1}ba)G' = baG' = bG'aG'$.

3.) Consider $\pi : G \longrightarrow G/N$. If $G/N$ is abelian, then $\pi(aba^{-1}b^{-1}) = e$, hence $G' < N$. Conversely, if $G' < N$, we have a surjective homomorphism $G/G' \rightarrow G/N$. $G/G'$ is abelian, hence so is it homomorphic image $G/N$. □

Definition 2.8.9. We can define the the commutator inductively, i.e. $G^{(2)} := (G')'$, etc. The $G^{(i)}$ is called the $i$-th derived subgroup of $G$. It’s clear that $G > G' > G^{(2)} > \ldots$.

A group is solvable is $G^{(n)} = \{e\}$ for some $n$.

Example 2.8.10.

Take $G = S_4$. The commutator is the smallest subgroup that $G/G'$ is abelian. Since the only non-trivial normal subgroups of $S_4$ are $V, A_4$.

It’s clear that $G' = A_4$. (Or one can prove this by hand). Similarly, one finds that $G^{(2)} = A_4' = V$, and $G^{(3)} = \{e\}$. Hence $S_4$ is solvable. □

Another useful description of solvable groups is the groups with solvable series.
Definition 2.8.11. A group $G$ has a subnormal series if there is a series of subgroups of $G$

$$G = H_0 > H_1 > H_2 > ... > H_n,$$

such that $H_i < H_{i-1}$ for all $1 \leq i \leq n$.

A subnormal series is a solvable series if $H_n = \{e\}$ and $H_{i-1}/H_i$ is abelian for all $1 \leq i \leq n$.

A subnormal series is a normal series if all $H_i$ are normal subgroups of $G$.

Theorem 2.8.12. A group is solvable if and only it has a solvable series.

Proof. It’s clear that $G > G' > ... G^{(n)} = \{e\}$ is a solvable series. It suffices to prove that a group with a solvable series is solvable. Suppose now that $G$ has a solvable series $\{e\} = H_n < ... < H_0 = G$. First observe that $G' < H_1$ since $G/H_1$ is abelian. We claim that $G^{(i)} < H_i$ for all $i$ inductively. Which can be proved by the observation that the intersection of the series $\{e\} = H_n < ... < H_0 = G$ with $G^{(i)}$ gives a solvable series of $G^{(i)}$. □

Example 2.8.13.

A finite $p$-group has a solvable series, hence is solvable.

Moreover, a nilpotent group is solvable. To see this, let $G$ be a nilpotent group. Then there exist a series

$$\{e\} < C_1(G) := Z(G) < C_2(G) < ... < C_n(G) = G.$$  

Notice that $C_{i+1}(G)/C_i(G) = Z(G/C_i(G))$ is abelian. Therefore this is a solvable series. □
